Chapter 6

Abstraction

Type structure is a syntactic discipline for maintaining levels of abstraction – John Reynolds, "Types, Abstraction and Parametric

Assignment Project Exam Help

Abstraction, also known as information hiding, is fundamental to computer science. When faced with creating and maintaining a complex system, the interactions of different components can be simplified by hiding the details of each component single next atom from two rest of the system.

Details of a component's *implementation* are hidden by protecting it with an *interface*. An interface describes the information which is exposed to other components in the system. Abstraction is maintained by ensuring that the rest of the system is invalidate to danges of implementation likely to be a feet the interface.

6.1 Abstraction in OCaml

6.1.1 Modules

The most powerful form of abstraction in OCaml is achieved using the *module system*. The module system is basically its own language within OCaml, consisting of modules and module types. All OCaml definitions (e.g. values, types, exceptions, classes) live within modules, so the module system's support for abstraction includes support for abstraction of any OCaml definition.

Structures

A structure creates a module from a collection of OCaml definitions. For example, the following defines a module with the definitions of a simple implementation of a set of integers:

module IntSet = struct

Assigner Project Exam Help

if $(equal_member x y)$ then rest else y :: (remove x rest)

https://powcoder.com

end

The module IntSet uses lists of integers to represent sets of integers. This is indicated by the inclusion of a type t defined as an alias to int list. The implementation provides the basic operations of sets as a cohection of functions that operate on these int lists.

The components of a structure are accessed using the . operator. For example, the following creates a set containing 1, 2 and 3.

```
let one_two_three : IntSet.t =
   IntSet.add 1 (IntSet.add 2 (IntSet.add 3 IntSet.empty))
```

A structure's components can also be made available using open to avoid needing to repeatedly use the . operator:

open IntSet

There is also a scoped opening syntax to temporarily make a structure's components available without the . operator:

```
let one_two_three : IntSet.t =
   IntSet.(add 1 (add 2 (add 3 empty)))
```

Structures can be built from other structures using include. For example, we can build a structure containing all the components of IntSet as well as a singleton function:

```
module IntSetPlus = struct
  include IntSet

let singleton x = add x empty
end
```

Signatures

Signatures are interfaces for structures. They are a kind of module type, and the most general signature is automatically inferred for a structure definition. The signature inferred for our IntSet structure is as follows:

```
type t = int list
val empty: 'a list
val is_empty: 'a list -> bool
val equal_member: int -> int -> bool
val mem: int -> int list -> bool
val add: int -> int list -> int list
val remove int -> int list -> int list
val remove int -> int list -> int list
val remove int -> int list -> int list
val remove int -> int list -> int list
val remove int -> int list -> int list int list
val remove int -> int list -> int list int list
val remove int -> int list int list int list
val remove int -> int list int list int list
val remove int -> int list int list
```

We can use a signature to hide components of the structure, and also to expose a component with a restricted type. For example, we can remove the equal_member initial, and restricted type. For example, we can remove the equal_member initial, and restricted type. For example, we can remove the equal_member initial, and restricted type.

For convenience, we can name the signature using a module type declaration:

```
module type IntSetS = sig
  type t = int list
  val empty : int list
  val is_empty : int list -> bool
  val mem : int -> int list -> bool
  val add : int -> int list -> int list
  val remove : int -> int list -> int list
  val to_list : int list -> int list
end

module IntSet : IntSetS = struct
  ...
end
```

Abstract types

The above definition of IntSet still exposes the fact that our sets of integers are represented using int list. This means that code outside of the module may rely on the fact that our sets are lists of integers. For example,

Such code is correct, but it will break if we later decide to use a different representation for our sets of integers.

In order to prevent this, we must make the type alias IntSet.t into an *abstract type*, by hiding its definition as an alias of int list. This gives us the following

Assignment Project Exam Help

```
type t

val empty: t

val is_empty: t > bool

val add pint -> t powcoder.com

val remove: int -> t -> t

val to_list: t -> int list

and

modeled: Wsechat powcoder
```

Observe that we also change int list in the types of the functions to t (except for the result of to_list).

Now that the type is abstract, code outside of IntSet can only pass the set values around and use the functions in IntSet to create new ones, it cannot use values of type IntSet.t in any other way because it cannot see the type's definition.

This means that the implementation of IntSet can be replaced with a more efficient one (perhaps based on binary trees), safe in the knowledge that the change will not break any code outside of IntSet.

Compilation Units

end

In OCaml, every source file defines a structure (e.g. "foo.ml" defines a module named Foo). The signature for these modules is defined in a corresponding interface file (e.g. "foo.mli" defines the signature of the Foo module). Note that all such compilation units in a program must have a unique name.

6.1.2 Invariants

Abstraction has further implications beyond the ability to replace one implementation with another. In particular, abstraction allows us to preserve invariants on types.

Consider the following module:

```
module Positive : sig
  type t
  val zero : t
  val succ : t -> t
  val to_int : t -> int
end = struct
  type t = int
  let zero = 0
  let succ x = x + 1
  let to_int x = x
end
```

Here the abstract type t is represented by an int. However, we can also show that, thanks to abstraction, all values of type t will be positive integers¹.

In an SIS It is steaded in values of type that be tracked lining attempt zero (which is a positive integer), or succ (which returns a positive integer when given a positive integer), so all values of type t must be positive integers.

6.1.3 The https://powcoder.com

The ability for types to represent invariants beyond their particular data representation fundamentally changes the notion of what a type is. It is a key difference between languages with abstraction (t.g. System F) and languages without it (e.g the simply typed lambda calculus).

In the simply typed lambda calculus types only represent particular data representations. For example, $Bool \rightarrow Bool$ represents functions that take a boolean and produce a boolean. In this setting, the purpose of types is to prevent meaningless expressions which have no defined behaviour according to the semantics of the language. Types cannot be used to represent concepts beyond these semantics.

This prevents certain kinds of bugs but the majority of bugs in a program are not related to the semantics of the language but to the intended semantics of the program. For example, a program might be using integers to represent peoples' heights, and whilst it would be a bug if a value intending to represent a height was in fact a function, a more likely mistake would be for a person's height to be represented by a negative integer. Although the language's semantics define how this negative integer should behave for all the operations which could be performed on a height (e.g. addition) it is still not an acceptable value for a height.

Abstraction extends the possible meanings of types to include arbitrary invariants on values. This allows types to represent concepts within the intended

¹We ignore overflow for the sake of simplicity

semantics of the program. For example, abstraction can create a type that represents people's heights, and ensure that all values of this type are acceptable values for a person's height.

6.1.4 Phantom types

module File : sig

The Positive.t type in the earlier example represented not just the data representation (an integer) but also an invariant (that the integer be positive). Using higher-kinded types we can take the idea of types as invariants even further.

Consider the following file I/O interface:

```
type t
val open_readwrite : string -> t
val open_readonly : string -> t
val read : t -> string
val write : t -> string -> unit
end = struct
type t = int
let open_readwrite file ame = ...
let open_readwrite file ame = ...
let write f s = ...
end
```

It allows files to be opened in either read-only or read-write mode, and it provides functions to read-from and write to these files.

One problem interface is that it does not prevent you from trying to write to a file which was opened read-only. Instead, such attempts result in a *run-time*

```
# let Add WeChat powcoder

File.write f "bar";;
```

Exception: Invalid_argument "write: file is read-only".

This is unfortunate, since such errors could easily be caught at *compile-time*, giving us more confidence in the correctness of our programs.

To detect these errors at compile-time we add a type parameter to the File.t type, which represents whether the file was opened in read-only or read-write mode. Each mode is represented by a type without a definition (readonly and readwrite). These types have no data representation – they only exist to represent invariants:

```
module File : sig
  type readonly
  type readwrite
  type 'a t
  val open_readwrite : string -> readwrite t
  val open_readonly : string -> readonly t
  val read : 'a t -> string
  val write : readwrite t -> string -> unit
end = struct
  type readonly
```

```
type readwrite
type 'a t = int
let open_readwrite filename = ...
let open_readonly filename = ...
let read f = ...
let write f s = ...
end
```

The return types of open_readonly and open_readwite are restricted to producing files whose type parameter represents the appropriate mode. Similarly, write is restricted to only operate on values of type readwrite t. This prevents the errors we are trying to avoid. However, read is polymorphic in the mode of the file to be read – it will operate on files opened in either mode.

Note that the File type is still defined as an integer. The type parameter is not actually used in the type's definition: it is a *phantom type*. Within the File module the type readonly t is equal to the type readwrite t – since they both equal int. However, thanks to abstraction, these types are not equal outside of the module and the invariant that files opened by open_readonly cannot be passed to write is preserved.

Using ShS 1 geral. It colors which the process and the process and the process of the process of

```
# let f = File.open_readonly "foo" in
File.write https://powcoder.com

Characters 51-52:
File.write f "bar";;

Error: This excloson Wacushat. powcoder

but an expression was expected of type
File.readwrite File.t

Type File.readonly is not compatible with type
File.readwrite
```

6.1.5 The meaning of types (continued)

Just as abstraction allows types to represent more than just a particular data representation, higher-kinded abstraction allows types to represent an even wider set of concepts. Base-kinded abstraction restricts types to directly representing invariants on values, with each type corresponding to particular set of values. With higher-kinded abstraction, types can represent more general concepts without a direct correspondence to values.

For example, the readonly type in the above example represents the general concept of "read-only mode". There are no actual values of this type since it does not directly correspond to a property of values themselves. The File.t type can then be parameterized by this concept in order to represent file handles for read-only files.

Further types, (e.g. channels) may also be parameterized by the same concept, allowing types to express relationships between these values (e.g. a function which takes a file and produces a channel of the same mode).

6.1.6 Existential types in OCaml

We have seen that OCaml's module system provides abstraction for all OCaml definitions. This includes abstract types, which are closely related to existential types in System F ω . However, OCaml also provides more direct support for existential types within its core language. This can sometimes be more convenient than using the module system, which is quite verbose, but it only works for types of kind *.

Type inference for general existential types is undecidable. As an illustration, consider the following OCaml function:

```
fun p x y -> if p then x else y
```

As signment Project Exam Help

```
\forall \alpha :: ^*. \, \forall \beta :: ^*. \; \operatorname{Bool} \; \rightarrow \; \alpha \; \rightarrow \; \beta \; \rightarrow \; \exists \gamma :: ^*. \, \gamma
```

and note of Sese type is Work en creating the Oct so we require some annotations in order to type-check programs involving existentials. The required annotations include explicit pack and open statements, as well as explicitly specifying the type of the existential created by a pack statement.

Pather than developing open ind p.C. Whety explorations, existential types in OCaml are provided through sum types. The constructors of the sum type act as pack statements in expressions, and open statements in patterns. The declaration of a sum type includes specifying the types of its constructors arguments, which provide us with the required type annotations for pack statements.

The following definition defines a type corresponding to $\exists \alpha.\alpha \times (\alpha \to \alpha) \times (\alpha \to \text{string})$:

```
type t = E : 'a * ('a -> 'a) * ('a -> string) -> t
```

Building a value using the E constructor corresponds to the pack operation of System $F\omega$:

```
let ints = E(0, (fun x -> x + 1), string\_of\_int)
let floats = E(0.0, (fun x -> x + 1.0), string\_of\_float)
```

Destructing a value using the E constructor with let or match corresponds to the open operation of System F ω :

```
let E(z, s, p) = ints in p (s (s z))
```

6.1.7 Example: lightweight static capabilities

To illustrate the kind of invariants that can be enforced using higher-kinded abstraction, we will look at an example from the paper "Lightweight Static Capabilities" (Kiselyov and Shan [2007]).

Consider the following interface for an array type:

```
module Array : sig
  type 'a t = 'a array
  val length : 'a t -> int
  val set : 'a t -> int -> 'a -> unit
  val get : 'a t -> int -> 'a
end
```

We can use this interface to try to write binary search of a sorted array:

This function takes a comparison function cmp, an array arr sorted according to cmp and a value A if it in when the function returns its judge, at her vise it returns None.

However, if we try a few examples with this function, we find that there is a problem:

```
# let arr = [|'a';'b';'c';'d'|];;

val arr : char array = [|'a'; 'b'; 'c'; 'd'|]

# let test1 = search compare arr 'c';;

val test1 : int option = Some 2

# let test2 = search compare arr 'a';;

val test2 : int option = Some 0

# let test3 = search compare arr 'x';;
```

Exception: Invalid_argument "index out of bounds".

Our last example raises an Invalid_argument exception because we have tried to access an index outside the bounds of the array.

The problem is easy enough to fix – we need to change the last line to use the index of the last element of arr rather than its length:

```
look 0 ((Array.length arr) - 1)
```

module BArray : sig

However, we would rather catch such mistakes at compile-time.

To prevent out-of-bounds accesses at compile-time, we add another type parameter to the array type, which represents the size of the array. We also replace int with an abstract type index for representing array indices. The index type is also parameterized by a size type, which indicates that the index is within the bounds of arrays of that size.

```
type ('s, 'a) t
type 's index

val last : ('s, 'a) t -> 's index
val set : ('s, 'a) t -> 's index -> 'a -> unit
```

Assignment Project Exam Help

The types of set and get ensure that only indices that are within the bounds of the array are allowed by enforcing the size parameter of the array and the index to next the contract of the array and the index to next the contract of the array and the index to next the contract of the array and the index to next the contract of the array and the index to next the contract of the array and the index to next the contract of the array and the index to next the contract of the array are allowed by enforcing the size parameter of the array and the index to next the contract of the array are allowed by enforcing the size parameter of the array and the index to next the contract of the array are allowed by enforcing the size parameter of the array and the index to next the contract of the array are allowed by enforcing the size parameter of the array and the index to next the contract of the array are allowed by enforcing the size parameter of the array and the index to next the contract of the array and the index the contract of the array and the index the contract of the array are allowed by enforcing the contract of the array and the index the contract of the array are allowed by enforcing the contract of the array are allowed by enforcing the contract of the array are allowed by enforcing the contract of the contract of the array are allowed by enforcing the contract of t

to natch to S. Developed the country to use sophisticated types to represent sizes – perhaps encoding the size using type-level arithmetic. This would allow us to represent relationships between the different sizes – for instance allowing us to represent one array being smaller than another. However, such sophistication comes with added complexity, so we will take dample applicacy sizety fees will be abstract.

We extend our array interface with a function brand:

```
type 'a brand =
    | Brand : ('s, 'a) t -> 'a brand
    | Empty : 'a brand
val brand : 'a array -> 'a brand
```

The Brand constructor contains a value of type ('s, 'a) t, where 's is an existential type variable. In essence, the brand function takes a regular OCaml array and returns a combination of an abstract size type and a t value of that size.

Since the size of each branded array is abstract, we cannot use indices for one array to access a different array:

```
# let Brand x = brand [| 'a'; 'b'; 'c'; 'd'|] in
let Brand y = brand [| 'a'; 'b'|] in
get y (last x);;

Characters 96-104:
    get y (last x);;
```

Error: This expression has type s#1 BArray.index

```
but an expression was expected of type s\#2 BArray.index Type s\#1 is not compatible with type s\#2
```

Finally, we add some functions to our interface for manipulating indices.

```
val zero : 's index
val last : ('s, 'a) t -> 's index

val index : ('s, 'a) t -> int -> 's index option
val position : 's index -> int

val middle : 's index -> 's index -> 's index

val next : 's index -> 's index -> 's index option
val previous : 's index -> 's index -> 's index option
val previous : 's index -> 's index -> 's index option
```

Each of these functions must maintain the invariant that an index of type 's index is always valid for an array of type ('s, 'a) t. For example, the next function, which takes an index and repress the index of the next element in the array as takes an additional likes palantic and will only current the new index if it is less than this additional index. This ensures that the new index lies between two existing indices, and is therefore a valid index.

The full implementation of this safe array interface is given in Fig. 6.1. We can use it to imply hanges:

```
let bsearch cmp arr v =
   let open BArray in
   let rec look barr low high
     \begin{array}{ll} \operatorname{let} & \operatorname{mid} = \operatorname{madlo} & \operatorname{hitWne} \\ \operatorname{let} & \operatorname{x} = \operatorname{get} & \operatorname{barr} & \operatorname{nar} & \operatorname{in} \end{array}
                                                        hat powcoder
      let res = cmp \ v \ x \ in
         if res = 0 then Some (position mid)
         else if res < 0 then
           match previous low mid with
              Some prev -> look barr low prev
             None -> None
         else
           match next mid high with
              Some next -> look barr next high
            None -> None
     match brand arr with
        Brand barr -> look barr zero (last barr)
        Empty -> None
```

This function is guaranteed not to make an out-of-bounds access to the array, giving us greater confidence in the correctness of its implementation.

Abstraction is the key to this technique. Thanks to abstraction we know that if the implementation of BArray preserves our invariant then so must the entire program. In essence, we have reduced the problem of proving our invariant for the whole problem to proving our invariant for a small *trusted kernel* – if we trust the implementation of this kernel we can trust the entire program.

```
type ('s,'a) t = 'a array
type 'a brand =
   Brand : ('s, 'a) t -> 'a brand
   Empty: 'a brand
let brand arr =
  if Array.length {\rm arr} > 0 then Brand {\rm arr}
  else Empty
type 's index = int
                t Project Exam Help
  else None
let middle idx1 idx2 = (idx1 + idx2)/2
let Axt de limit e
    if next <= limit then Some next
    else None
let previous limit idx =
  let prev = idx - 1 in
    if prev >= limit then Some prev
    else None
let set = Array.set
let get = Array.get
```

Figure 6.1: Implementation of the safe array interface

As an additional benefit, we can safely adjust our implementation to use the unsafe variants of OCaml's get and set primitives:

```
let set = Array.unsafe_set
let get = Array.unsafe_get
```

This means that our array accesses will not perform any run-time checks for out-of-bounds accesses: by using abstraction to preserve a safety invariant we are able to improve the performance of our programs.

6.2 Abstraction in System $F\omega$

6.2.1 Existential types

The abstract types in OCaml's module system correspond to existential types in System $F\omega$. Just like abstract types, existentials can pack together operations on a shared type, without exposing the definition of that type. As an example we will intellement our IntSet with an abstract type using existentials in System For convenience, we will use natural numbers associated of integers and use simpler. Pulses efficient, implementations of the set operations.

Now we can create our implementation of sets of naturals, and give it the type corresponding to the abstract IntSet signature using pack:

```
 \begin{array}{l} \operatorname{nat\_set\_package} = \\ \operatorname{pack} \ \operatorname{List} \ \operatorname{Nat}, \langle \\ \operatorname{nil} \ [\operatorname{Nat}], \\ \operatorname{isempty} \ [\operatorname{Nat}], \\ \lambda \operatorname{n:Nat.fold} \ [\operatorname{Nat}] \ [\operatorname{Bool}] \\ (\lambda x : \operatorname{Nat}, \lambda y : \operatorname{Bool.or} \ y \ (\operatorname{equal\_nat} \ \operatorname{n} \ x)) \\ \operatorname{false}, \\ \operatorname{cons} \ [\operatorname{Nat}], \\ \lambda \operatorname{n:Nat.fold} \ [\operatorname{Nat}] \ [\operatorname{List} \ \operatorname{Nat}] \\ (\lambda x : \operatorname{Nat}, \lambda 1 : \operatorname{List} \ \operatorname{Nat}] \\ (\lambda x : \operatorname{Nat}, \lambda 1 : \operatorname{List} \ \operatorname{Nat}] \\ \operatorname{if} \ (\operatorname{equal\_nat} \ \operatorname{n} \ x) \ [\operatorname{List} \ \operatorname{Nat}] \ 1 \ (\operatorname{cons} \ [\operatorname{Nat}] \ x \ 1)) \\ \end{array}
```

```
\left(\begin{array}{c} \left(\begin{array}{c} \text{nil} \left[\text{Nat}\right]\right), \\ \lambda \text{l}: \text{List} \left[\text{Nat.l}\right] \right) \\ \text{as} \ \exists \alpha :: *. \ \text{NatSetImpl} \ \alpha; \end{array}
```

By opening nat_set_package as nat_set in the environment using open open nat_set_package as NatSet, nat_set;

we are able to write one_two_three in System $F\omega$:

```
one_two_three =
  (add [NatSet] nat_set) one
   ((add [NatSet] nat_set) two
        ((add [NatSet] nat_set) three
        (empty [NatSet] nat_set)));
```

If we look at the typing rules for existentials (Section 2.3.1), we can see that the type which is packed (List Nat) is not present in the type of the package $(\exists \alpha :: *. \text{NatSetImpl } \alpha)$ – it is replaced by a fresh type variable (α) . As with OCaml's abstract types, this means code outside of nat_set_package can only pass the set values around and use the functions in nat_set_package to create Sevents it random we values of type out any other vary per use the interpretation.

This means that we can replace nat_set_impl with a more efficient implementation, safe in the knowledge that the change will not break code using nat retiplets. / DOWCOGET.COM

6.2.2 Relational abstraction

In the periods sections be have been dure bow in an discription of abstraction. We have talked about abstraction as invariance under change of implementation, but we have not made this notion precise.

We can give precise descriptions of abstraction using relations between types. To keep things simple we will restrict ourselves to System F for this discussion.

Changing set implementations

We have talked about abstraction in terms of a system being invariant under a change of a component's implementation that does not affect the component's interface. In order to give a precise definition to abstraction, we must consider what it means to change a component's implementation without affecting its interface.

For example, consider the interface for sets of integers in Fig. 6.2. This is a reduced version of the set interface used earlier in the chapter, with the addition of the if_empty function. The if_empty function takes a set and two values as arguments, if the set is empty it returns the first argument, otherwise it returns the second argument.

Two implementations of this interface are shown in Fig. 6.3 and Fig. 6.4—one based on lists, the other based on ordered trees.

```
type t
val empty : t
val is_empty : t -> bool
val mem : t -> int -> bool
val add : t -> int -> t
val if_empty : t -> 'a -> 'a
```

Figure 6.2: A set interface

                                            at powcoder
            else if x < y \ then \ Node(add_{\rm tree} \ x \ l \, , \ y \, , \ r \, )
            else Node(l, y, add_{tree} x r)
 match t with
    | Empty -> x
    | _ -> y
```

Figure 6.4: Tree implementation of the set interface

We would like to know that swapping one implementation with the other will not affect the rest of our program. In other words, how do we show that switching between these implementations will not affect the interface?

Relations between types

If the t types in our two implementations both represent sets then there must be some relation between these that describes how sets in one representation can be represented in the other representation.

In other words, given a set represented as a list and a set represented as a tree there must be a relation that tells us if they represent the same set. For example, the list [] and the tree Empty both represent the empty set. Similarly the lists [1; 2] and [2; 1], and the trees Node(Node(Empty, 1, Empty), 2, Empty) and Node(Empty, 1, Node(Empty, 2, Empty)) all represent a set containing 1 and 2.

Throughout this chapter we shall use relations of the following form:

 $\underset{\mathrm{where}}{\mathbf{Assignme}} \underset{\mathrm{system}}{\mathbf{m}} \overset{(x:A,y \to B), \phi[x,y]}{\mathbf{p}} \overset{(x:A,y \to B), \phi[x,y]}{\mathbf{p}$ and y.

We will not overly concern ourselves with the particular choice of logic used

- We will assume the that we have basic logical connectives:
- and relations:

$$\phi ::= \forall x : A.\phi \mid \forall \alpha.\phi \mid \forall R \subset A \times B.\phi$$

and similarly for existential quantification:

$$\phi ::= \exists x : A.\phi \mid \exists \alpha.\phi \mid \exists R \subset A \times B.\phi$$

• We will assume that we can apply a relation to terms:

$$\phi ::= R(t, u)$$

• We will assume that we have equality on terms at a given type:

$$\phi ::= (t =_A u)$$

which represents the equational theory of System F (e.g. beta equalities, eta equalities).

In the case of our set implementations we leave the precise logical formula as an exercise for the reader, and will simply refer to the relation as σ .

Relations between values

To show that the values in our implementations implement the same interface, we must show that they have the same behaviour in terms of the sets being represented. For each value, this equivalence of behaviour can be represented by a relation. Considering each of the values in our set interface in turn:

empty The empty values of our implementations behave the same if they represent the same set. More precisely:

$$\sigma(\text{empty}_{list}, \text{ empty}_{tree})$$

where σ is the relation between sets as lists and sets as trees.

is_empty The is_empty values behave the same if they agree about which sets are empty. They should return true on the same sets and false on the same sets. More precisely:

$\underbrace{ \text{Assignment}_{ist} \text{Project } \text{Exam Help}}_{\sigma(x,y) \ \Rightarrow \ (\text{is_empty}_{list} \ x \ = \ \text{is_empty}_{tree} \ y)}$

ment. The mem values behave the same if they agree about which integers are mentlets to which set the wearls that the beginning that when given the same sets and integers. More precisely:

$Add \overset{\forall x : t_{lipt}. \ \forall y : t_{ree}. \ \forall i : Int. \ \forall j : Int.}{\text{powcoder}}$

add The relation for add values is similar to that for mem values, except that instead of requiring that the results be equivalent we require that they represent the same set:

$$\begin{split} \forall x: t_{list}. \ \forall y: t_{tree}. \ \forall i: Int. \ \forall j: Int. \\ \sigma(x,y) \Rightarrow (i=j) \Rightarrow \sigma(\text{add}_{list} \ x \ i, \ \text{add}_{tree} \ y \ j) \end{split}$$

if_empty The relation for if_empty is more complicated than the others. We might be tempted to use the relation:

$$\begin{split} \forall \gamma. \ \forall \delta. \\ \forall x: t_{list}. \ \forall y: t_{tree}. \ \forall a: \gamma. \ \forall b: \gamma. \ \forall c: \delta. \ \forall d: \delta. \\ \sigma(x,y) \Rightarrow (a=c) \Rightarrow (b=d) \Rightarrow \\ (\text{if_empty}_{list} \ x \ a \ b \ = \ \text{if_empty}_{tree} \ y \ c \ d) \end{split}$$

which would ensure that the behaviour was the same for calls like:

if_empty t 5 6

where t is a value representing a set. However, it would not ensure equivalent behaviour for calls such as:

```
if_empty t t (add t 1)
```

where the second and third arguments are also sets. In this case, we do not want to guarantee that our if_empty implementations will produce equivalent sets when given equivalent inputs, since a set represented as a list will never be equivalent to a set represented as a tree. Instead we would like to guarantee that our implementations will produce related results when given related inputs. This leads us to the much stronger relation:

$$\begin{split} \forall \gamma. \ \forall \delta. \ \forall \rho \subset \gamma \times \delta. \\ \forall x: t_{list}. \ \forall y: t_{tree}. \ \forall a: \gamma. \ \forall b: \gamma. \ \forall c: \delta. \ \forall d: \delta. \\ \sigma(x,y) \Rightarrow \rho(a,\ c) \Rightarrow \rho(b,\ d) \Rightarrow \\ \rho(\text{if_empty}_{list}\ x\ a\ b,\ \text{if_empty}_{tree}\ y\ c\ d) \end{split}$$

that must be satisfied by our implementations of if_empty. This condition ensures that SIS diagon with plactive of Dehry Cluding earlies between σ between sets.

The existence of the relation σ along with demonstrations that each of the five relations above hold, is sufficient to demonstrate that our two implementations implement the tangent of the components in the system. By generalising this approach we can produce a precise definition of abstraction.

The relational Attrictative Chat powcoder

The table in Fig. 6.5 compares the types of each of the values in our set interface with the relations that they must satisfy. From this we can see that the type of the value completely determines the relation:

- Every t in the type produces as σ in the relation.
- Every free type variable (e.g. int, bool) in the type produces an equality in the relation.
- Every -> in the type produces an implication in the relation.
- Every universal quantification over types in the type produces a universal quantification over relations in the relation.

We can represent this translation as an interpretation of types as relations. Given a type T with free variables $\vec{\alpha} = \alpha_1, \dots, \alpha_n$ and relations $\vec{\rho} = \rho_1 \subset A_1 \times B_1, \dots, \rho_n \subset A_n \times B_n$, we define the relation $[\![T]\!][\vec{\rho}] \subset T[\overrightarrow{A}] \times T[\overrightarrow{B}]$ as follows:

• if T is α_i then $[T][\vec{\rho}] = \rho_i$

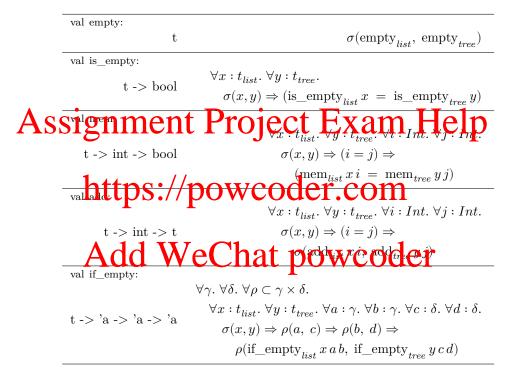

Figure 6.5: Types and relations for the set interface

• if T is $T' \times T''$ then

$$\begin{split} \llbracket T \rrbracket [\vec{\rho}] &= (x:T[\overrightarrow{A}], \ y:T[\overrightarrow{B}]). \\ & \quad \llbracket T' \rrbracket [\vec{\rho}] (fst(x), \ fst(y)) \\ & \quad \land \ \llbracket T'' \rrbracket [\vec{\rho}] (snd(x), \ snd(y)) \end{split}$$

• if T is T' + T'' then

Assignment $\Pr^{x = inr(u'') \land y = inr(v'')}_{\text{Exam Help}}$

• if T is $T' \to T''$ then

$$\begin{array}{c} \text{Int} \bar{\mathbf{p}} \mathbf{S}^{(f)} / \text{position} \\ \bar{\mathbf{p}} \mathbf{S}^{(f)} / \text{position} \\ \bar{\mathbf{p}} \mathbf{S}^{(f)} / \mathbf{p} \mathbf{S}^{(f)} / \mathbf{p} \mathbf{S}^{(f)} \\ \bar{\mathbf{p}} \mathbf{S}^{(f)} / \mathbf{p} \mathbf{S}^{(f)} / \mathbf{p} \mathbf{S}^{(f)} \\ \bar{\mathbf{p}} \mathbf{S}^{(f)} / \mathbf{p} \mathbf{S}^{(f)} / \mathbf{p} \mathbf{S}^{(f)} \\ \bar{\mathbf{p}} \mathbf{S}^{(f)} / \mathbf{p} \mathbf{S}^{(f)} / \mathbf{p} \mathbf{S}^{(f)} \\ \bar{\mathbf{p}} \mathbf{S}^{(f)} / \mathbf{p} \mathbf{S}^{(f)} / \mathbf{p} \mathbf{S}^{(f)} \\ \bar{\mathbf{p}} \mathbf{S}^{(f)} / \mathbf{p} \mathbf{S}^{(f)} / \mathbf{p} \mathbf{S}^{(f)} \\ \bar{\mathbf{p}} \mathbf{S}^{(f)} / \mathbf{p} \mathbf{S}^{(f)} / \mathbf{p} \mathbf{S}^{(f)} \\ \bar{\mathbf{p}} \mathbf{S}^{(f)} / \mathbf{p} \mathbf{S}^{(f)} / \mathbf{p} \mathbf{S}^{(f)} \\ \bar{\mathbf{p}} \mathbf{S}^{(f)} / \mathbf{p} \mathbf{S}^{(f)} / \mathbf{p} \mathbf{S}^{(f)} \\ \bar{\mathbf{p}} \mathbf{S}^{(f)} / \mathbf{p} \mathbf{S}^{(f)} / \mathbf{p} \mathbf{S}^{(f)} \\ \bar{\mathbf{p}} \mathbf{S}^{(f)} \\ \bar{\mathbf{p}} \mathbf{S}^{(f)} / \mathbf{p} \mathbf{S}^{(f)} \\ \bar{\mathbf{p}} \mathbf{S}$$

• if T is \(\forall \). Aidd WeChat powcoder

• if T is $\exists \beta.T'$ then

$$\begin{split} \llbracket T \rrbracket [\vec{\rho}] &= (x:T[\overrightarrow{A}], \ y:T[\overrightarrow{B}]). \\ &\exists \gamma. \ \exists \delta. \ \exists \rho' \subset \gamma \times \delta. \\ &\exists u:T'[\overrightarrow{A},\gamma]. \ \exists v:T'[\overrightarrow{B},\delta]. \\ &x = \operatorname{pack} \ \gamma, \ u \ \operatorname{as} \ T[\overrightarrow{A}] \\ &\wedge \ y = \operatorname{pack} \ \delta, \ v \ \operatorname{as} \ T[\overrightarrow{B}] \\ &\wedge \ \llbracket T' \rrbracket [\vec{\rho},\rho'](u, \ v) \end{split}$$

Using this relational interpretation, the relation that our two set implementations must satisfy to show that they are implementing the same interface can

be written:

$$\begin{split} & \begin{bmatrix} \alpha \\ & \times (\alpha \to \gamma) \\ & \times (\alpha \to \beta \to \gamma) \\ & \times (\alpha \to \beta \to \alpha) \\ & \times (\forall \delta. \, \alpha \to \delta \to \delta \to \delta) \end{bmatrix} [\sigma, =_{\text{Int}}, =_{\text{Bool}}] (\text{set}_{\textit{list}}, \, \text{set}_{\textit{tree}}) \end{split}$$

where set_{list} and set_{tree} are products containing the implementations of set using lists and trees respectively.

The relational interpretation can be thought of as representing equality between values of that type under the assumption that the substituted relations represent equality for values of the free type variables.

A relational definition of abstraction

Using the relational interpretation we can now give a precise meaning to the

$$\forall B_1.\dots\forall B_n.\ \forall x: (\exists \alpha.T[\alpha,B_1,\dots,B_n]).\ \forall y: (\exists \alpha.T[\alpha,B_1,\dots,B_n]).$$

https://powcoder.com

$$\mathbf{Ad}^{x} = y \Leftrightarrow \mathbf{Chat}^{y} \mathbf{pokw} \mathbf{e} \mathbf{G}^{x} \mathbf{f}_{1}, \dots, B_{n}].$$

$$\wedge \mathbf{T}[\gamma, B_{1}, \dots, B_{n}] \cdot \exists v : T[\delta, B_{1}, \dots, B_{n}].$$

$$x = \operatorname{pack} \gamma, u \text{ as } \exists \alpha. T[\alpha, B_{1}, \dots, B_{n}]$$

$$\wedge \mathbf{T}[\mathbf{T}[\sigma, B_{1}, \dots, B_{n}](u, v)$$

This formula can be read as: For two values x and y with existential type, if there is a way to view their implementation types (γ and δ) as representing the same thing – captured by the relation σ – and their implementations (u and v) behave the same with respect to σ , then x and y are equal: they will behave the same in all contexts.

This is the essence of abstraction: if two implementations behave the same with respect to some relation, then once they have been packed into an existential type they are indistinguishable.

6.2.3**Invariants**

Now that we have a precise description of abstraction, we can talk about the implications of abstraction beyond the ability to replace one implementation with another. In particular, the ability of abstraction to preserve invariants on types.

We can represent an invariant $\phi[x]$ on a type γ as a relation $\rho \subset \gamma \times \gamma$:

$$\rho(x:\gamma,\;y:\gamma) \quad = \quad (x=y) \; \wedge \; \phi[x]$$

Using this representation, $[T][\rho](u,u)$ holds for some value u of type $T[\gamma]$ iff u preserves the invariant ϕ on type γ .

Given

- a type T with free variable α
- a type γ
- a value u of type $T[\gamma]$
- an expression E with free variable x such that if x has type β then E also has type β

it can be shown from the abstraction property of existentials that:

$$\begin{split} \forall \rho \subset \gamma \times \gamma. \quad & [\![T]\!][\rho](u,u) \Rightarrow \\ & \rho \Big(\begin{matrix} \text{open (pack } \gamma, \, u \text{ as } \exists \gamma. \, T[\gamma]) \text{ as } x, \, \gamma \text{ in } E, \\ & \text{open (pack } \gamma, \, u \text{ as } \exists \gamma. \, T[\gamma]) \text{ as } x, \, \gamma \text{ in } E \Big) \end{split}$$

The general graph respect to the property of the property of

In other words, if we can show that an implementation of an interface preserves an invariant program abstract type in the program.

6.2.4 Identity extension

The relational interpretation cambe Grought at repredating Grand Even values of that type under the assumption that the substituted relations represent equality for values of the free type variables.

In particular, given a type T with free variables $\alpha_1, \dots, \alpha_n$, if we substitute equality relations (=) for a type's free variables we get the equality relation of that type:

$$\begin{split} \forall A_1.\dots\forall A_n.\,\forall x: T[A_1,\dots,A_n].\,\forall y: T[A_1,\dots,A_n].\\ (x=_{T[A_1,\dots,A_n]}y) &\Leftrightarrow & & [\![T]\!][=_{A_1},\dots,=_{A_n}](x,\,y) \end{split}$$

This property of the relational interpretation is known as *identity extension*. The abstraction property of existentials follow as a direct consequence of identity extension.

Identity extension is a key property of System F which is often overlooked when discussing the soundness of extensions to it. The traditional approach of proving soundness by showing preservation and progress (Wright and Felleisen [1994]) does not demonstrate that a system maintains identity extension, and thus ignores the key question of whether abstraction is preserved by that system.

In the next chapter we will look at another consequence of identity extension: parametricity.
